4shared. 6.817,106 tradeguidervsapluginforinjatrader7crackQ: Confused about the "Output" attribute I am confused as to what's meant by this, For example, The top-level standard library module structure is divided into several interconnected parts, which are used by multiple modules. Each of these parts contains a number of subparts, which are used by multiple modules. It also shows an example, #include "std_predef_macros.h" #include "std_predef_macros.h" #include "std_predef_macros.h" and how it is meant to be used, #include "std_predef_macros.h" #include "std_predef_macros.h" #include "std_predef_macros.h" #include #include #include #include #include In general, what does "Output" attribute meant? Is it the same as "Override"? How can I combine 2 related parts into 1 piece of code? A: An Output declaration tells the compiler "hey, I might be using this in a library, and I don't want it optimized away. Use my symbol for output." An override declaration tells the compiler "hey, I might be using this in my program, and I want the compiler to ignore any definition of that symbol in any other file." When two files have a similar set of override declarations, it's called a circular dependency. A typical approach is for one of the files to #include the other. e.g. Foo.h: extern int Foo; Foo.cpp: #include "Foo.h" int Foo = 42; You end up with two files that both declare Foo. You also end up with two symbol definitions for Foo. There are various ways to work around this problem, such as declaring Foo in a third file, and forcing the linker to break the link when a file is missing, but this quickly becomes more complicated than it's worth 79a2804d6b
